Service Atlas

Designed to help ABB Sales Engineers and Service Product Managers understand, manage, and communicate complex service offerings for frequency converters.

The project explores how data, services, customer values, and scenarios can be translated into a shared actionable system that supports both strategic decision-making and real-time customer conversations.

Team project · 5 months

ABB Motion manages a wide and complex portfolio of service products for frequency converters, spanning different drive types, life-cycle stages, customer segments, and regional contexts.

Service Product Managers (S.P.M.) are responsible for defining, updating, and evaluating services, while Sales Engineers (S.E.) must translate this information into clear and value-based recommendations during pre-sales discussions.

This information was scattered across spreadsheets, documents and internal systems, making it difficult to assess service potential, compare offerings, or communicate value consistently. The design challenge was to create a shared digital tool that enables both roles to define, visualize, and use the service portfolio.

Desk Research

Reviewed service documentation, value models, and installed drive data.

System Mapping

Mapped relationships between drives, services, workflows, and customers.

User Research

Interviewed S.E. and S.P.M. on daily workflows and decision-making.

Benchmarking

Analyzed comparable internal tools and patterns for design consistency.

Research*

*To respect confidentiality, all drive and service names have been anonymized.

Research supported every phase of the project and evolved iteratively alongside the design.

We started with extensive desk research on ABB documentation, including service matrices, customer value frameworks, and drive lifecycle data. This allowed us to understand both the structure of the portfolio and the language used internally.

In parallel, we developed the system map to translate this information into a relational model. User research with ABB stakeholders helped validate assumptions about daily workflows, decision-making processes, and pain points.

Finally, benchmarking against ABB's own tools and comparable analytical platforms informed interaction patterns, hierarchy, and tone.

Structuring complexity

Documentation

Interviews

SPM

We mapped the entire service ecosystem to understand how products, services, customer values, and business logic relate to one another. The system map structured this complexity into three core domains: Drives, Services, and Customers.

In parallel, interviews with S.E. and S.P.M. revealed a tension between the need for speed and clarity in customer-facing interactions (S.E.) and the need for depth and analytical control at a portfolio level (S.P.M.), showing that a single interface would fail to serve both roles.

Concept

One system, two perspectives

The core concept is a shared service intelligence platform with two complementary views: one for Sales Engineers and one for Service Product Managers. Both roles access the same underlying data, but interact with it differently.

For Sales Engineers, the platform supports scenario-based exploration, filtering services by customer needs, drive characteristics, and values.

For Service Product Managers, the platform emphasizes portfolio oversight, service analytics, and controlled editing.

	1. Trigger	2. Access	3. Setup	4. Action	5. Outcome
 Service Product Manager	New analytics, market signals, or feedback highlight a portfolio opportunity or issue	Access the Service Atlas and browse Managed Services	Review service performance, lifecycle coverage, and business relevance across drives and regions.	Update service characteristics, refine scenarios or values, or create a new service proposal.	Changes are saved, approved, and communicated to Sales Engineers through updates and notifications.
 Sales Engineer	A customer meeting, issue, or a notification about a new or updated service.	Access the internal Service Atlas to verify updates and service details; transitions to the customer-facing interface during meetings.	Define customer situation by scenario, drive characteristics, and customer priorities.	Explore and compare relevant services, adjusting options live during the conversation.	A clear, value-based service recommendation is proposed to the customer.

Main Features Overview

Sales Engineer

Offering Exploration

Centralized overview of relevant services, with scenario-, value-, and drive-based filters to identify suitable offerings for customer discussions.

Service Cards

Structured service pages provide clear value propositions and technical scope, enabling fast comparison between alternative service offerings.

Main Features Overview

Performance Dashboard

Analytical dashboard presenting service performance, delivery metrics, and geographic distribution, with direct access to service attributes for editing.

Service Product Manager

Comparative Analysis

Side-by-side comparison of services within the portfolio to assess positioning, performances, overlaps, and differentiation across drive types and scenarios.

Main Features Overview

Relations Map

Simpler visual overview of the service portfolio, designed to support customer conversations by clearly showing how services relate to values, scenarios, and drive contexts at a glance.

Customer-facing Interface

Graph Views

Interactive visual comparisons that place services across selected values and parameters, helping customers understand positioning and differences between services.

Validation

Testing interface variations across scenarios

We validated the platform through scenario based user testing with experienced ABB Sales Engineers and Service Product Managers, asking them to perform realistic tasks such as proposing services during pre-sales discussions or reviewing and updating service offerings.

Testing also highlighted opportunities to improve visual clarity and speed of insight, directly informing iterative refinements.

Alongside the core solution, we explored a range of both familiar and more experimental visualization approaches to assess different ways of representing service relationships, values, and insights. Testing these variations helped us understand how different visual strategies support clarity, exploration, and decision-making.

Extracted insights directly inform design iterations

- Showing Service history of customer or geographical views to get a more comprehensive analysis
- Having more visualization styles in the database
- Price should be capture in value because it is one of the important element which helping in making a decision process for customer
- Suggested to using diagram or graph to visualize the value also statistic instead of description
- Make it faster and easier to better understand the context
- Having a way to reset the filters rapidly
- Understanding the lifecycle stage of the customer's drive is also important so S.E know what is urgent
- Show some history actions, rather than database
- Find the most important infos to display, to ensure attention will not distracted
- Don't directly display the detailed information of the service card. Instead, display it first with ICONS and titles.
- Deliver a richer content experience per screen to reduce unnecessary scrolling.
- Think of the platform as mainly analytical, less as an editing tool (?)
- To see where service is being used (Geographically) → So more insights on the different aspect of service
